Object Manipulation using a Humanoid Robot

El Sayed M. Saad, Medhat H. Awadalla, Hosam Eldin I. Ali, Rasha F. A. Mostafa

Abstract—Interaction with its environment is a key requisite for a humanoid robot. Especially the ability to recognize and manipulate unknown objects is crucial to successfully work in natural environments. Visual object recognition, however, still remains a challenging problem. To get the robot capable of identifying the geometric shapes and colors of the objects, a vision system is proposed. The paper proposes a natural language understanding system also, where the robot will be able to effectively communicate with human through a dialogue developed in Arabic language. The developed dialogue and a dynamic object model are used for learning the semantic categories and object descriptions. In this paper, a robot will be developed to interact with the users performing some specified actions. Moreover, integration between the proposed vision and natural language understanding systems has been presented. Finally, a voice-based dialogue between the user and robot will be developed. Intensive experiments have been conducted indoor to address the validity of the complete proposed system. The achieved results show that the overall system performance is high compared with the related literature to the theme of this paper.

Index Terms—Vision System, Speech system, object category recognition, Object Detection, Color detection, Natural Language Understanding, Ontology, Syntax, knowledge Representation, Semantic Networks, Motion System.

I. INTRODUCTION

Humans are the most advanced creatures of the nature. It is believed that humanoid robots will be the most advanced creatures of humans. Among the man-made creatures such as automobile hand-phones and multimedia devices, robots of future will hopefully be the most ideal assistants to human beings [1]. In the future we will see “personal robots” that will entertain, comfort and serve people in their private lives and homes. While presently robotic servants or butlers exist only in the form of early prototypes in a few research laboratories, they are expected to become as ubiquitous as PCs in the future [2-4]. The necessary functions for the task are understanding users’ commands, recognizing user-specified objects by vision, and manipulating objects [5].

An important aspect of humanoid robots in a natural environment is the ability to acquire new knowledge through learning mechanisms, which enhances an artificial system with the ability to adapt to a change or new environment. In contrast to the most offline learning algorithms applied in machine learning today, online algorithms need to be performed automatically, and through interaction with the environment or with other agents/humans. Here, in this paper, the proposed vision system and dialogue offer the appropriate means. The fact that robots have to be autonomous in such a way that they should do everything without the intervention of humans. Since the proper system is the good vision system, so the question arises here is: how to develop a robot that can see like a human? For many applications in robot vision interested in locating the object by giving it a distinctive color from the surrounding environment as an application to recognize the ball in pitch between two teams of humanoid soccer robot team [6, 7], using laser, sonar, or using camera for robot vision system, or learning to classify objects into categories in human development. Such ability is crucial for robots that should operate in human environments where object categorization skills are required to recognize complex object categories (e.g., metal objects, empty bottles, etc.) [8]. However in this paper, robots will learn how to distinguish among different geometric shapes of square, rectangular, circle, and triangular objects picked up via a camera mounted on the robot and also identify their colors.

The paper also focuses on the distinction of robot to a command given by user in Arabic language. Using the Arabic language syntax for imperative sentence and establishment of dialogue to identify the objects that does not exist in the database. In this paper, we address learning of unknown objects in dialogue, which enables a robot to acquire information about unknown objects, and stores this information in a knowledge base. A typical problem will be raised is that non-trivial information must be communicated, such as when the user enters an imperative syntax error, or there are new words in the written sentence that cannot be understood by the system. Thus, the dialogue system should conduct interaction strategies for learning in such way that the information about the object can successfully be communicated. In addition, it has to cope with new words, grammatical and semantic levels to achieve the learning goal. It should create a model of the object’s semantics, which describes the type, color, shape, properties of the object and its function. All previous data will be addressed using Arabic language. Moreover, this paper adds question syntax of Arabic language. Finally, using a special tool developed to convert any answer of robot to Arabic speech. Also, in this paper, a prototype of simple humanoid robot circuit was constructed and tested for implementing the concepts and programs described in this paper. The remainder of this paper is organized as follows: Section 2 gives an overview of the proposed system comprising the proposed vision system architecture, the natural language understanding system architecture, the integration of them, and the motion system. Section 3 presents experiments and discussion. Section 4 concludes the paper.

II. THE PROPOSED SYSTEM

The proposed system, as shown in figure (1), consists of the following sub-systems:

1. Vision Sub-system.
2. Natural Language Understanding Sub-system.
3. Merging Sub-system.

**1. Vision Sub-system**

There are things that attract any child such as colors and geometric shapes of objects, once the child taught how to distinguish between them using one word that defines each shape and color. He could recognize them by himself later on. The main aim of the proposed system is to make robots behave as child, once it is learned the skill of how to recognize object’s shape such as square, rectangle, circle, or triangle, and its color such as red, black, white, blue, green,… etc., seen by its camera. It could detect the object’s shape and its color by itself seen later in any image taken by his camera at different places. The proposed vision system has the following procedure and is demonstrated in the flowchart shown in figure 2.

The vision system procedure:

**A. Acquiring Image**

Images taken from the robot’s camera can easily be fed to Matlab program using the ‘videoinput’ function. This function makes it possible to assign a variable as a video input. Image processing cannot be performed on a video input, so single frames should be extracted from the video with a frame grabber [9]. A so-called snapshot is taken out of the video input and this single image is used for object and color detection.

![Fig.3. Result of converting image to black and white](image2.png)

**B. Image Manipulation**

![Fig.4. Result of edge detection](image3.png)

Color detection

The black and white image is converted into edge image, as shown in figure (4), using ‘edge’-function [9].

**C. Edge detection**

The black and white image is converted into edge image, as shown in figure (4), using ‘edge’-function [9].

**D. Image Segmentation**

The previous image is used to find the boundary of each object by using ‘boundaries’-function [9]. These indices are used to cut the black and white image to a set of images, each of which contains only one item, as shown in figure 5, each image is then used to determine the object’s shape and color.

![Fig.5. The segmented object image](image4.png)

**E. Identification of the shape of an object**

There are many ways to determine the location of the element, including the mean and variance of number of ones in an image. However, the previous methods cannot determine the shape of the object; three main colors, namely Red, Green, and Blue. This color space can be visualized as a 3d matrix. Each image is converted into black and white then the image is filtered to remove any added noise due to lighting. A well-known noise filter is the median filter. In Matlab, this filter can be used with the ‘medfilt2’-function [9], as shown in figure 3.
Accordingly, a new method is proposed that calculates the difference between the number of ones in each row. If it always increases, the object’s shape will be a triangle, or if it increases before the middle line and then decreases after the middle line of the object, the object’s shape will be a circle, and if it does not change, the object is a square or a rectangle, it depends on the dimensions of the image as shown in figure 6. All written functions are based on ‘diff’-function [9].

The previous procedure has been applied to the image shown in fig. 7, and the achieved results confirm the validity of the proposed approach. All results identified the color and shape of the object and it is given to the user in syntax of Arabic Language.

2. Natural Language Understanding System Sub-system

An interactive learning for artificial systems has been addressed in several systems. However, the number of approaches that allow interactive knowledge acquisition for humanoid robots is still comparably small [10]. This paper focuses on how to establish a dialogue between the user and the robot especially if some of the commands to the robots are not pre-defined. Furthermore, the paper concentrates on how the robot will understand the commands on syntax of the Arabic language, to address these issues, the natural language understanding system is proposed as shown in figure 8. The proposed system has the following components:

![Fig.8. Natural Language Understanding System Overview](image)

A. The form of imperative sentence syntax

First sentence is entered into the system in the form of imperative syntax; imperative syntax of the Arabic language takes more than one form as shown in figure 9.a. The input sentence is divided into a set of tokens, and then the affix such as "ال" added at the beginning of the word or "ى" added at the end of the word is omitted. Moreover, the proposed system has ability to take a question from user about the place of the object using a question tool of "أين". The question is entered into the system in the form of question syntax; the question syntax of the Arabic language takes more than one form as in shown in figure 9.b, it begins with "أين".

![Fig.9.a. Example of the form of imperative sentence syntax](image)

B. Ontology

Our ontology inspired from the work in [10, 11], however it is applied to the Arabic language, as shown in figure 10, and also we have added that the object is classified by its color and shape.

![Fig.9.b. Example of the form of question syntax](image)
Object Manipulation using a Humanoid Robot

Knowledge representation is an area in artificial intelligence that focuses on the design of formalisms which can explicitly represent knowledge about a particular domain, and the development of reasoning methods for inferring implicit knowledge from the represented explicit knowledge. Semantic network form a family of knowledge representation formalisms which can be used to represent and reason with conceptual knowledge about a domain of interest. For the classification of each object and storing its data in the database, we used semantic network [12]. A semantic network is a simple representation scheme that uses a graph of labeled nodes and directed arcs to encode knowledge [13,14]. Information type and semantic categories of objects are modeled in ontology. The object ontology provides inheritance information and defines properties that can be associated with objects. Moreover, our ontology for objects’ locations inspired by the work in [15], however it is applied to Arabic language as shown in figure 11. User should store objects’ locations found in the environment in the database using "بجانب","على","فى","تحت","أمام","خلف","تخت","في","على","جنب", "أمام","خلف","تخت" as shown in figure 10.b.

C. Dialogue

Dialogue begins when the robot does not find the object in its database, or the user enters an imperative syntax error. Dialogue is in a form of questions and answers words, mutual between the user and robot in Arabic as shown in figure 11. User can ask the robot to describe the scene in the front of itself in terms of the shapes of the objects and their colors by using the developed vision program just by pressing a key called the vision system in the developed interface shown in figure 10.a.

In all the above cases, if the robot could not recognize the object because it is not in its database or the user entered a syntax error, or, robot does not find objects' place in its database, a dialogue between the user and the robot will start, the user will answer some questions as shown in figure 12.d, and then the database will be adapted to accommodate the new information. If the same command sent to the robot, or the robot is asked again for identifying the same object, the system will be able to identify it.

Fig.11. Dialogue sample

3. Merging Sub-system

Merging between the vision and the natural language understanding systems is implemented by regular usage of GUI using Visual BASIC 6.0, where it appears to the user interface screen. One of the major problems faced most of previous researchers is the linking between Matlab environment and Visual Basic to have a reasonable interface for the users. In this paper, all programs have been developed in Prolog, and the Dynamic Link Library is implemented in such way that it can deal directly with Visual Basic programs.

The developed interface gives the user different capabilities to choose as follows:

1- The user can ask the robot to describe the scene in the front of itself in terms of the shapes of the objects and their colors by using the developed vision program just by pressing a key called the vision system in the developed interface shown in figure 12.a.

2- The user can ask the robot to identify or fetch a particular object, the robot will use the developed Natural Language Understanding System to search about the object in its database. If it is recognized, the robot writes to the user that object is found. Then the object features will be sent to the vision system to recognize its shape and Color, as shown in figures 12.b and 12.c.

3- The user can ask the robot about the object's place, the robot will use the developed Natural Language Understanding System to search about the object in its database. If it is recognized, the robot writes to the user that the object place as shown in figures 12.e and 12.f. Then the object will be sent to the vision system to recognize its shape and Color.

In all the above cases, if the robot could not recognize the object because it is not in its database or the user entered a syntax error, or, robot does not find object's place in its database, a dialogue between the user and the robot will start, the user will answer some questions as shown in figure 12.d, and then the database will be adapted to accommodate the new information. If the same command sent to the robot, or the robot is asked again for identifying the same object, the system will be able to identify it.
The previously mentioned subsystems are interdependent. It is not enough to equip the robot with basic functionalities for dialogue comprehension and production to make it interact naturally in situated dialogues. We also need to find meaningful ways to relate language to be spoken, and enable the robot to use its perceptual experience to continuously learn and adapt itself to the environment. And cover speech recognition, where the dialogue...
between the user and robot will be voice based. For this purpose we used a tool to convert Arabic text of robot answer to voice, this tool called MbrolaTools35. This tool is well described in [16]. We used it to convert the answer of robot appeared to user to speech heard by user. When answer is written to user it will hear at the same time, this by pass this text to MbrolaTools35 as seen in Figure (13.a, 13.b), however the screen appears in figure 13.b will be invisible for the user. User will hear the voice immediately when it appears at text box. Also the dialogue between user and robot shown in figure 12.d changed to be not only based on text but also voice based.

5. Motion Sub-System

If it is required to build human-like robots that can interact naturally with people, our robots must know not only the properties of objects but also to move toward objects or to make just gesture that it find the object's place. This gesture in our proposed system is to turn the robot camera to object's location. This challenging task has been done in two phases; First phase is to develop an algorithm to detect location of object in an image taken by the robot camera. Secondly is to construct a prototype circuit considered as robot face moving on simple motor considered as robot neck. So our proposed motion system has two software and hardware phases.

1. **Software phase:**

The proposed motion system has the following procedure and it is demonstrated in the flowchart shown in figure (14).

The first three stages in the flowchart have mentioned in section (2.A.a, 2.A.b, 2.A.c).

**A. Split image to two halves**

The previous image taken from the previous stages is used to find the total size of the image using 'size' function [13, 8]. Then by dividing this size by two to have two parts of the image as seen in figure (15).

**B. Object Dimension Detection**

The previous image taken from the previous stages is used to find the boundary of each object by using 'boundaries' function [13]. These indices are used to know dimension of each object.

**C. Finding the object's place**

If the object dimensions found in the right half of the image, the program will send number one to the motion circuit using serial port connected from the computer to the circuit using 'serial' function [13] else if it found in the left side of the image.
The program will send number two to the motion circuit else the program will not output any data to the circuit.

As mentioned in section 2.C.1, 2.C.2, and 2.C.3, user can ask the robot about the object's place and the robot will use the developed Natural Language Understanding System to search about the object in its database. If it is recognized, the robot will inform the user about the place of the object and then the object shape and color will be sent to the vision system to recognize it in the robot scene and robot will flash on the object telling user that the object place is found. In this moment the software phase added will issue a reasonable command to the hardware to make robot to turn right or left as will be discussed in the following section.

2. Hardware Phase

Due to the lack of commercially available humanoid robots, multi-agent research with real humanoid robots was not feasible so far. While a quite number of research labs construct their own humanoids and it is likely that some advanced humanoid robots will be commercially available in the near future. So we construct our own prototype of humanoid robot. This hardware is a simple robot consists of motor considered as neck and camera considered as robot eye as shown in figure (16.a).

![Humanoid robot prototype](image1.png)

**Fig.16.a. Humanoid robot prototype**

To combine the software phase with our hardware to allow the robot to interact with a set of objects with different types and sizes and allow robot to turn his head according to the number issued from the software algorithm, we design an interface card as seen in figure (16.b) to convert this number into motion. This motion gets the robot neck to turn right or left. This motion has been performed using a stepper motor carry on its head a camera. This card has been connected to a PC using serial to USB converter cable as shown in figure 16.c and 16.d.

III. EXPERIMENTS AND DISCUSSION

Intensive experiments have been conducted to address the validity of the proposed systems. First, we have tested the vision program in several stages to check its accuracy. Initially, it is tested on still images, and then pictures from a camera held on the laptop, the destination in an interview of an embodiment of the kitchen, and the kitchen components, such as door, window, a cup and also a piece of cheese cooked. Background with one color, black, is chosen. The achieved results from the vision program have a remarkable precision as shown in figure 17, although the vision affected by the camera resolution, and lighting. Our camera resolution used was (640*480). Furthermore, the achieved results show that the accuracy of natural language understanding program is also reasonable even for different users as long as they know the basics of Arabic. We provide a comparison with Holzapfel et al., [10] as shown in table II.

IV. FUTURE WORK

The work of this paper will be extended so that the robot can determine a suitable place for the user to put things, and also provide a road map to the user towards that place. In addition to, a real robot will be constructed to test the proposed approaches in real environments and applications.
