

# To Find Solution for Secure and Fast Data transfer: Improving Network Performance

Ashvini Jadhav, Shrinivas Gadage

**Abstract**—The theory of network coding promises significant benefits in network performance, especially in lossy networks and in multicast and multipath scenarios. To realize these benefits in practice, we need to understand how coding across packets interacts with the acknowledgment (ACK)-based flow control mechanism that forms a central part of today's Internet protocols such as transmission control protocol (TCP). The mechanism for TCP/NC that incorporates network coding into TCP with only minor changes to the protocol stack, thereby allowing incremental deployment. how the source transmits linear combinations of packets currently in the congestion window. And new interpretation of ACKs the sink acknowledges every degree of freedom even if it does not reveal an original packet immediately. Thus, new TCP ACK rule takes into account the network coding operations in the lower layer and enables a TCP-compatible sliding-window approach to network coding. Coding essentially masks losses from the congestion control algorithm and allows TCP/NC to react smoothly to losses, resulting in a novel and effective approach for congestion control over lossy networks such as wireless networks

Wireless networks and communications have emerged as a dominant mode of communications, technical advances in wireless communications has brought faster and more affordable network access. However, the technological advances are often matched, if not outmatched, by users appetite for even faster, cheaper, and more robust wireless networks. For instance, with the rise of new forms of data, in particular high quality multimedia, we are faced with a challenge of transforming our communication networks to handle unparalleled growth in traffic and strict delay constraints. In order to meet the future demands, we need to manage the existing wireless networks more efficiently in terms of, but not exclusively, energy, latency, and bandwidth; and to build new infrastructure

and design novel protocols that take into account the high-bandwidth, dynamic, and diverse traffic that needs to be served across wired and wireless medium. There are several sources of challenges in designing a robust wireless networks, which are not as prominent in wired networks.

- Wireless is a shared medium They ultimately have to share either in time, frequency, or space. When senders and receivers fail to share the wireless medium appropriately, we observe a collision or an interference, which hinders efficient communication.
- Wireless is stochastic in nature The time varying nature of wireless results in not only ever-changing capacity and delay but also errors and erasures.
- Wireless is a broadcast medium Wireless networks are often insecure, prone to adversarial eavesdropping and contamination attacks.

These properties of wireless make designing and operating wireless networks vastly different from those of wired networks. However, our currently deployed wireless networks not adequately address these problems. Often measures to address the problems of wireless networks are appended to the existing architecture. For instance, the current design to combat erasures and errors is retransmission

## A Motivation

Motivated by these observations, propose system build more efficient, high performance wireless networks. In this dissertation, Present algorithms that can better manage interference, overcome losses, and provide secure communications by recognizing and harnessing the characteristics of wireless.

## B Key Idea

The key idea behind this dissertation is in understanding that wireless networks are fundamentally different from wired networks, and recognizing that directly applying techniques from wired networks to wireless networks limits throughput and performance. Network coding promises a fundamentally new way to operate networks. At present, the intermediate nodes can only store, forward, or replicate the information they receive. This store-and-forward approach is closely related to the multi-commodity flow problem, and has been studied extensively owing to its wide applications to communication networks. network coding questions the fundamental assumption in our store and forward network designs. The theory of network coding, first introduced in their seminal paper by Ahlswede et al. [1], breaks the convention of router networks. Intermediate nodes,

Manuscript published on 30 October 2013.

**C Objective**

The objective of the Network Coding can benefit Internet communication. One goal of that improve Internet communication. Another goal is to gather information on the existing practical implementations of NC, common functionalities and propose a path to standardization of communication. To provide fast, secure, reliable and cost effective communication medium between multiple clients and server. To present a simplified server-multiple client architecture which enables multi cast messages with in a public/private channel.

**D Goal of Paper**

The goal of this task is to identify appropriate architectural considerations in applying networking coding techniques in different parts of the operation butterfly network. Modularity of design remains a key element of achieving successful deployment, operation, and maintenance of such systems. This dissertation shows that network coding is a powerful tool that can efficiently and effectively overcome interference, erasures. Network coding can deliver on the promise of a more efficient wireless network with higher throughput and reliability.

**II OVERVIEW OF NETWORK CODING**

Network Coding is a technique that can be used to improve a network throughput, efficiency and scalability, as well as resilience to attacks and eavesdropping, as compared to traditional methods.

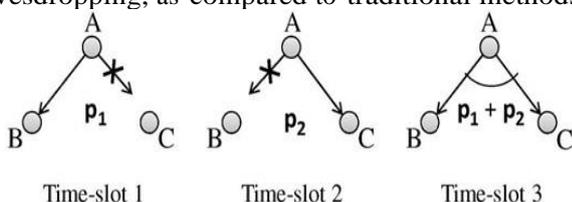

Fig. 1. Coding over a broadcast[19]

In Network Coding, data is manipulated inside the network or at the network edges to achieve the maximum possible information flow in a network, based on principles of Shannon Information Theory.

**A Network Coding Background**

Network coding has evolved significantly from its inception. Initially, network coding was proposed for wired multicast networks, in which one or more sources may wish to deliver information to many receivers. References [1] showed that, if additional computing tasks are performed at the intermediate nodes, the multicast capacity can be achieved.

In case of lost the packet, then a simple retransmission strategy may not be the best option, since the retransmission is useless from the viewpoint of the other receivers that have already received the packet. Fig 1 node A broadcasts 2 packets to nodes B and C. In the first time-slot, only node B receives packet p1 and in the second slot, only node C receives packet p2. At this point, if instead of retransmitting p1 or p2, node A is allowed to mix the information and send a single packet containing the bitwise xor of p1 and p2, then both B and C receive their missing packet in just one additional time slot. This example shows that

if allow coding across packets, it is possible to convey new information simultaneously to all connected receivers. as per this example if possible I can send multiple packet in one time slot just like parallel sending broadcasting format. The now standard example is the butterfly network from [1] as per, which is shown in Fig.

2. Here, node A wants to multicast a stream of packets to nodes F and G. Assume the links are error free with a capacity of one packet per slot. If all nodes are only allowed to forward packets, then node D can forward either the packet from B p1 or the one from C p2. It can be seen that alternating between these options gives a multicast throughput of 1.5 packets per slot.

However, if node D sends a bitwise xor of p1 and p2 as shown in the figure, then it is possible to satisfy both receivers simultaneously, resulting in a multicast throughput of two packets per time slot. This is the highest possible, since it meets the min-cut bound for each receiver.

1) Through the butterfly network example, Ahlswede et al. [1] introduced the field of network coding. With network coding, a node inside the network, instead of simply forwarding the incoming packets onto outgoing links, is now allowed to send a coded version of the incoming packets.

2) Although both the examples above use a bitwise xor code, the coding operation could be much more general  
i) The groups of bits as elements of a finite field, and a packet as a vector over this field.

ii) Coding could then correspond to performing linear combinations of these vectors, with coefficients chosen from the field of operation.

iii) In order to decode, the receiver will have to collect as many linear combinations as the number of packets that were mixed in, and then solve the resulting

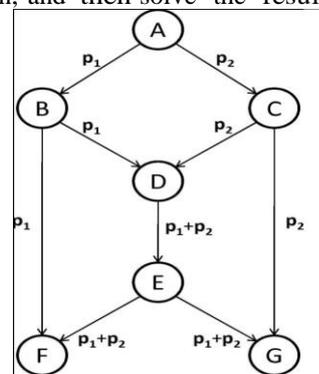

Fig. 2. Butterfly network[19]

system of linear equations by Gauss Jordan elimination. if ACK of packet receive as early as possible it avoid retransmission and it reduce traffic achieving successful deployment, operation, and maintenance of such systems. Thus, it may be useful

**A Related Activity**

In packet-based FEC content to support high assurance delivery of files or other data over unidirectional network path and support of multicast Negative-ACKnowledgement (NACK) based Automatic Repeat-re Quest (ARQ) protocols using packet erasure coding repair strategies.

- Both of these specifications support the use of different FEC encoding techniques. The following are topics of interest Research:
- 1) Performance bounds of NC and gains over non-NC communication
  - 2) Encoding techniques and their performance implications
  - 3) Open problems in NC research

### III NC PRACTICAL APPLICATION AND STANDARDIZATION PATH

Practical implementations, analyze their architecture and identify best/common approaches for the promising NC methods. The following are topics of interest in NC Implementation:

- Architectural considerations: control plane, forwarding plane and transport. The goal of this task is to identify appropriate architectural considerations in applying networking coding techniques in different parts of the operation butterfly network. Modularity of design remains a key element of to determine some appropriate mapping of different uses of network coding to different system functions. This includes the relationships between data transport, control plane, forwarding plane, and even layer 2 components. With emerging Software-Defined Networking (SDN) architecture being proposed and pursued, one topic of interest will be practical ways in which network coding might be accommodated in such systems. Additionally, SDN systems may actually offer opportunities for practical implementation of network coding concepts.

- End-to-end v.s hop-by-hop NC

Related to topic 1 (architectural considerations), there are specific considerations for the application of Network Coding for end-to-end versus hop-by-hop (or local scope) encoding and data delivery. For example, employment of Network Coding techniques by intermediate systems implies more sophisticated (stateful and/or complex) operation than typical existing packet forwarding operations. Additionally, the interrelationship between end-to-end delivery and hop-by-hop operations may require a richer interface than the present distinct protocol layers.

tandem with network-layer coding techniques also. There is recent interest in

”Content-based” or Information Centric Networking (ICN) and network coding can be a very compatible, supporting mechanism for this alternative form of networking. Additionally, in some cases it is possible for application-layer information encoding (e.g. data compression) and channel coding (i.e., network coding in this case) to be performed jointly for improved performance or utility.

- Throughput

The throughput of today's wireless networks is far from optimal. NC increases wireless throughput because 1) It uses a broadcast nature coding allows the coders to compress the transmitted packets based on information that are known at various nodes. By matching what each neighbor has with what another neighbor wants, a coder can deliver multiple packets to different sources in a single transmission. This type of transformation is named inter-flow network coding because the coding is done over packets that differ in their next hop, and thus from different flows.

Example: Today's people often listen to music in public

places. I can imagine a situation in which many people want to listen to their favorite music using common hot-spots. Efficient bandwidth usage is crucial in this type of scenario. Let's consider a situation in which two clients are users of this service. Each of them has some songs on their devices and want to listen to a song it does not have. In order to get the song a customer wants it also must present which songs it already has. So A, B are customers of the service, SA and SB songs which users A and B have on their devices. Now imagine that the user A wants to listen to the song SB, and the user B wants to listen to the song SA. Instead of sending the separate data streams to both of the users, the service point can broadcast XOR version of the stream. As the result both of the users can easily decode their songs as well as the access point can send half of the data required in the scenario. In this example network coding doubles the throughput.

- Reliability

In today's network by reliability we usually mean the retransmission of the packets in case of packet loss. This works quite well in wired networks, but seems to be inefficient in wireless ones. Network coding gives a new approach to reliability. As the result of mixing information, there are no special packets. To illustrate it, let's consider an example from a traditional approach. Without coding a source needs to know which packets the destination missed in order to retransmit them. In an unreliable environment it may consume some extra bandwidth. If we want to use network coding, we usually do not care about individual packets. A source needs to inform us only if it receives enough packets to decode the transmitted file. There is also one additional benefit, because of improved reliability it also improves throughput of the network (less data needs to be retransmitted).

- Monitoring

Network coding can be exploited to better monitor the link loss rate in wireless networks. Let's consider an example shown in 2. In the example nodes A, B, C, D, E, F are sensors while nodes G and H are sinks connected through a high-bandwidth link. When we use network coding nodes G and H may receive P1, P2, P1+P2 or nothing depending on the transmission on each link. By sending several rounds of probes from C and B. It observes link loss on all five links simultaneously, which leads to bandwidth and energy savings.

- Common Encoding Algorithms, Service Descriptions, and Packet Formats

When Network Coding is applied to Internet systems and possibly applied in different aspects of network operation, there may be utility in common encoding (and decoding) algorithms, service descriptions, and even packet (or other data unit) formats.

Proposed System In this section we introduce our protocol and elaborate on its main functional blocks

- 1) In current system coding decoding delay I try to reduce that delay of decoding packet a) Block level coding decoding,
- 2) Intermediate node is work for reencoding so I will provide security for that

3) When multiple paths are used in parallel, one important decision is how much of the traffic needs to be sent through each path. Multiple path Optimization with Fuzzy Logic

**A Coding Decoding module**

Modification for systems using network coding. 1) The key difference to be dealt with is that under network coding the receiver does not obtain

$T(s,t)$  be the maximum possible throughput from node S to node t. By the max-flow min-cut theorem  $T(s,t)$  is upper bounded by the minimum capacity of all cuts, which is the sum of the capacities of the edges on a cut, between these two nodes.

Karl Menger proved that there is always a set of edge-disjoint paths achieving the upper edges) C gives the capacity of each link of E. Let bound in a unicast scenario, known as the max-flow min-cut theorem.

**IV. LOGICAL DESCRIPTION**

In my project proposal is that coding operations occur not only at the end hosts but at intermediate node with 1)encoding decoding 2)Load balancing 3)Security ACK and RTT measurement control using packet loss as a congestion indicator is not well suited to this

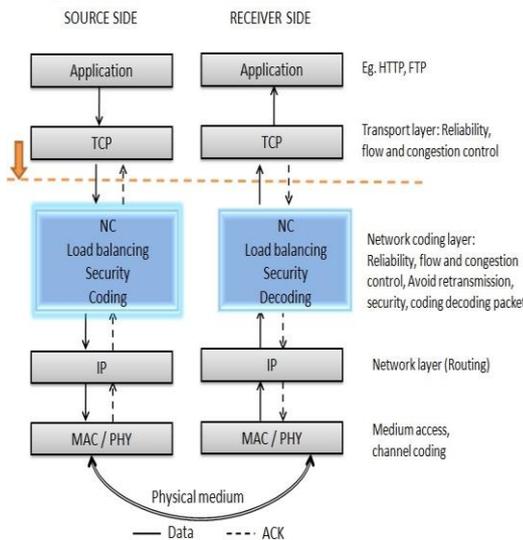

Fig. 3. NEW PROTOCOL STACK

situation. However, it is useful to note that the congestion related losses are also made to appear as a longer RTT. Therefore, Need an approach that infers congestion from an increase in RTT. The natural choice is TCP-Suit. TCP-Suit uses a proactive approach to congestion control by inferring the size of the network buffers even before they start dropping packets. The crux of the algorithm is to estimate the round-trip time (RTT) and use this information to find the discrepancy between the expected and actual transmission rate. As congestion arises, buffers start to fill up and the RTT starts to rise, and this is used as the congestion signal. This signal is used to adjust the congestion window and hence the rate. In order to use TCP-Suit correctly in this setting, Need to feed it the fictitiously longer RTT of a degree of freedom that includes the fictitious queuing delay. It introduces a novel RTT estimation algorithm to do this. The sender can note down the transmission time of every linear combination. When an ACK arrives, to which

transmission it should be matched in order to compute the RTT match it to the transmission that occurred after the one that triggered the previous ACK. Consider the example shown in The congestion, window is assumed to be 4 packets long. All 4 transmissions are linear combinations of the 4 packets in the window. In this example, the 1st packet is seen because of the 1st transmission. The 2nd and 3rd transmissions are lost, and the 4th transmission causes the 2nd packet to be seen (the discrepancy is because of losses). As far as the RTT estimation is concerned, transmissions 2, 3 and 4 are treated as attempts to convey the 2nd degree of freedom. The RTT for the 2nd packet is therefore computed based on the oldest such attempt, namely the 2nd transmission. In other words, the RTT is the difference between the time of reception of ACK=3 (in Figure 4), and the time of the transmission of  $(p1 + 2p2 + 2p3 + p4)$ .

**V. SIMULATION ENVIRONMENT**

We have simulated TCPNC by JAVA and compared with TCPNC, TCP-ACO, TCP protocol.

- Number of nodes Peer client: 8
- Server: 1
- Topology node 7 : Butterfly Network
- Packet size : 512

The following is the parameters used in the simulations. The network Butterfly network

- packet loss:
- Transmission speed :
- Duration simulation :
- Sender: IP Address of Sender
- Receiver: Multiple IP Address Receiver

**VI. SIMULATION RESULTS**

The following graphs shows the simulation results for TCP-ACO, TCPNC, TCP protocol. The Results are compared with TCP-ACO, TCPNC, TCP protocol. Blue line in graph shows results for TCP-ACO protocol, Red line in graph shows results for TCPNC protocol and Green line shows results for TCP protocol. From the graphs we come to know that results for TCPNC-ACO algorithm are better than TCP AND TCPNC in each aspect. It show that improve the throughput of network by using network coding 20

**VIII. CHALLENGES OF SYSTEM**

- 1) Extensions to Multipath and Multicast: Further work is needed to ensure that the different characteristics of the paths to the receiver (in case of multipath) or to multiple receivers (in case of multicast) are taken into account correctly by the congestion control algorithm.
- 2) Re-Encoding Packets at Intermediate Nodes: The case where intermediate nodes perform network coding. Theory suggests that a lot can be gained by allowing intermediate nodes to code as well.

Our scheme naturally generalizes to such situations. The ability to code characteristics of the underlying link. Ideally, the choice inside the network is important for multicast connections. of these parameters should be automated. For instance, the Even for a point-to-point connection, the ability to re-correct values could be learned dynamically based on encode at an intermediate node offers the flexibility of measurement of the link characteristics such as the link adding redundancy where it is needed, i.e., just before the loss rate, bandwidth, and delay. In addition, the parameters lossy link. The practical aspects of implementing re-have to be extended to cover the case of multipath transport and

IX. SNAPSHOTS OF NETWORK CODING

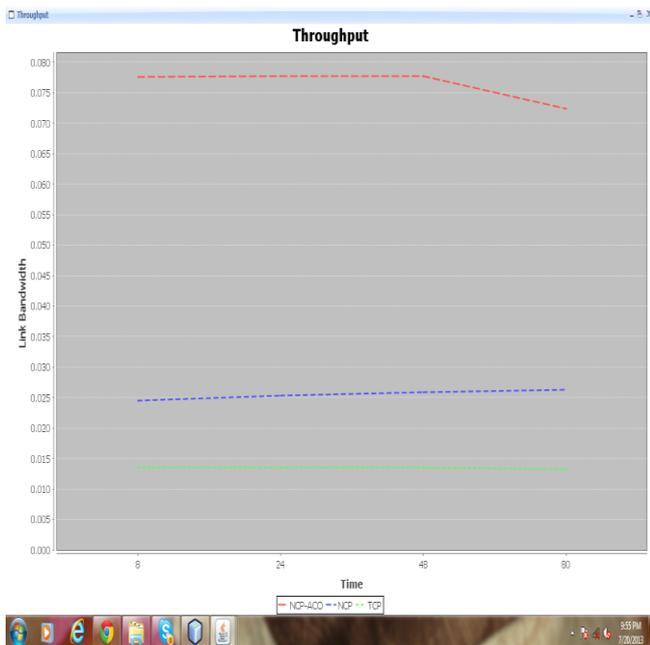

Fig. 5. Throughput Wired and wireless Network encoding need to be studied further. Multicast scenarios as well

3) Automatic Tuning of TCP/NC Parameters: More work is needed in the future for fully understanding the role played by the various parameters of the new protocol, Redundancy factor R and the coding window size W. several useful discussions.

X. CONCLUSION

Network coding key role in incorporating coding into the control algorithm. From an implementation perspective, introduce a new network coding layer between the

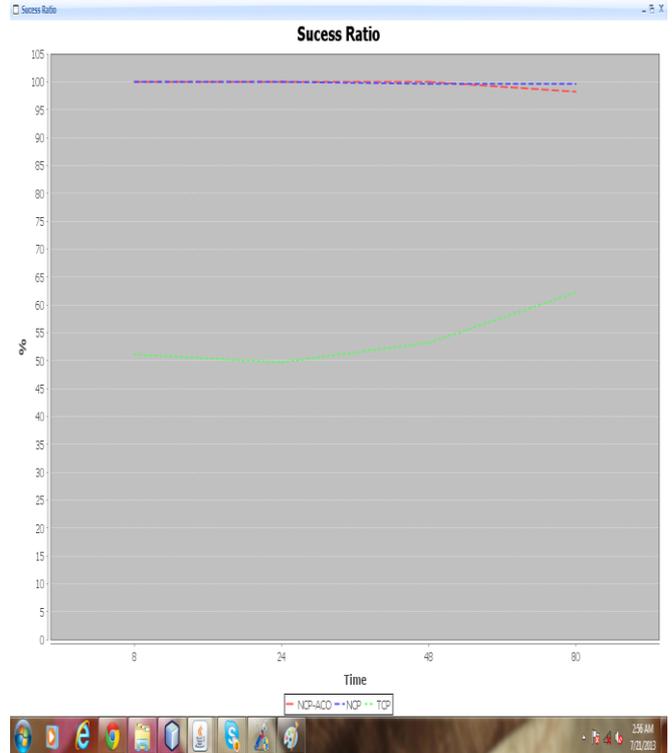

Fig. 8. Success ratio Wireless network network layers on both the source and receiver sides. Thus, changes can be easily deployed in an existing system. A salient feature of proposal is that coding operations occur only at the end hosts, thereby preserving the end-to-end philosophy of TCP. The overhead associated with the coding operations in a practical setting. Throughput gains are seen even though the intermediate nodes do not perform any coding. Theory suggests that a lot can be gained by allowing intermediate nodes to code as well. Quantifying the impact of such coding is of interest in the future. It presents a new framework for combining coding with feedback based rate-control mechanisms in a practical way. It is of interest to extend this approach to more general settings such as network coding based multicast over a general network 1) A feature of previous proposal is that coding operations occur only at the end hosts 2) In my project proposal is that coding operations occur not only at the end hosts but at intermediate node with 1)encoding decoding 2)Load balancing 3)Security
