An Analysis of User Behavior using Closed Set of Agglomerative Approach with GRC Constraints

Amit Kumar Chouksey, Mayank Namdev

Abstract: In the current scenario every Organization need to understand their customers’ behavior, preferences and future needs which depend upon past behavior. Web Usage Mining is an active research area in which customers session clustering is done to find out the customer’s activities. It investigates the problem of mining frequent pattern and especially focuses on reducing the number of rules using closed pattern technique. It also reduce scans the size of the database using Agglomerative clustering technique using partial database scan. It is perform by Profile based Closed Sequential Pattern Mining with Agglomerative Clustering. It searches the next request page in advance using only partial web data not in whole web data. There is an advantage to no need take input as number of cluster. So it utilized a personalized weighted recommendation system based on user’s interest with less execution time.

Keywords: Web Usage Mining, Prefix Span, Gap, Recency, Compactness, Data Stream, Closed Pattern, Data Mining, Personalization, Sequential Pattern Mining, Web Services, Agglomerative Clustering.

I. INTRODUCTION

The popular medium of publishing is the World Wide Web is very rich source of information gathering. It making sense of data is difficult because publication on the web is largely unorganized. Web mining is also knowledge extraction techniques which discover access patterns from the web. It is divided into three parts, a) web usage mining, b) web structure mining and c) web content mining. The commonly used data mining algorithms are Association Rule Mining (ARM), Sequential Pattern Mining, Clustering, and Classification.

An ARM technique is used to find out the rules between items found in a transaction database. In the context of web usage mining a transaction is a group of web page accesses with an item being a single page access. The problem of discovering sequential patterns is that of finding inter-transaction patterns such that the presence of a set of items is followed by another item in the time-stamp ordered transaction set. The data mining algorithms are used to generate the association rule between the items, sequential pattern of access of items, and clustering of items. Web Usage Mining (WUM) is the application of data mining techniques to large Web data repositories in order to produce results that can be used in the design tasks and improve response time.

Clustering analysis is used to find out those items that have similar characteristics and group into it. It manages the group of user information or data from Web server logs.

It also can facilitate the development and execution of future marketing strategies. It dynamically support or changing a particular site based on a visitor on a return visit. An application of existing data mining algorithms, e.g. discovery of association rules or sequential patterns, the overall task is not one of simply adapting existing algorithms to new data.

The WUM process is a file which having input from web user behavior as a user session files that gives an exact accounting of who accessed the website. It is also having the information just like what pages were requested and in what order, and how long each page was viewed. A user session is a time interval where a web user accesses the pages that occur during a single visit to a website. The web users access related all the information contained in a raw web server log. It does not reliably represent a user session file for a number of reasons. So that selectively information converts into tabular form and after that apply data mining technique. After getting result it produces some meaningful and useful information.

II. RELATED WORK

In 2013, Omar Zaarour, Mohamad Nagi [14] proposed an improvement of the web log mining procedure and to the prediction of online navigational pattern. It proposed for session identification using a refined time-out based heuristic. After detect the navigational pattern by using a specific density based algorithm. Now finally, a new proposed method for efficient online prediction is also recommended for applicability.

In 2016, Doddegowda B J, G T Raju, Sunil Kumar S Manvi [16] having approach to personalize the information available on the Web according to user requirements. It adjusts the information/services delivered by a Web to the needs of each user or group of users to find the behavioral patterns.

In 2016, Minubhai Chaudhari and Chirag Mehta [17] proposed a prefixspan algorithm with GRC constraints which generates sequential patterns by using prefix projected pattern growth approach. It uses gap, compactness and recency constraints during sequential pattern mining process. The gap constraint applies limit on the separation of two consecutive transactions of discovered patterns, recency constraint makes patterns to quickly adapt the latest behaviors and compactness constraint make sure reasonable time spans for the discovered patterns.

In 2016, Fan Muhan, Shao Sujie, and Rui Lanlan [18] proposes a method for mining the frequent closed patterns in a sliding window to capture information timely and accurately when new data stream arrives. Here each basic window is used to store the Closed Pattern-tree in sliding window updates which is incrementally updated and delete the infrequent or unclosed patterns.

In 2017, H. Ryang [19] propose a novel algorithm for finding high utility patterns in the list structure over data streams on the basis of a sliding window mode. It avoid the generation of candidate patterns to improve the efficiently works in complex dynamic systems.

In 2017 Bing Zhang and Guoyan Huang [20] proposed an approach to efficiently mine sequential pattern using influential functions based on software execution sequence. It can occur multiple times in a trace, which leads to high cost of time and extreme complexity of the research.

### III. ANALYSIS OF PREVIOUS WORK

The following table shows the analysis of previous and current work:

### IV. PROPOSED APPROACH

The proposed Profile based Closed Sequential Pattern Mining using Agglomerative Clustering approach is applied for discover frequent sequential patterns item in a cluster by using Agglomerative algorithm which produce the cluster of web data set. This cluster is used to access the partial web data set not whose web data set. So at this time this cluster data tree having the web pages of website in proportional sessions can access partially.
In this research it scan only partial database not the whole database so that multiple scanning of database will be reduced and response time is increases. It enhanced reflection of importance of pages by using min-max weight and support of every page by using min-max weight of pages updating automatically by using web services.

It is identifying the user previous search subjects and topics so that current search will be more up to the point. So information gathered could be used to offer feedback to users on their use of the internet. It enables the effective tracking for the development and also improvement of the user interface in software by analyzing user behavior.

In future work, other data mining algorithms can be implemented in cloud to efficiency handle big data of many Hospital website in distributed environment for finding any critical diseases.
