Design of a Robust Controller by LQG/LTR Formalism for Francis hydro Turbine Driving a Synchronous Generator

Yeremou Tamtsia Aurélien, Nneme Nneme Léandre, Samba Aimé Hervé

Abstract: This paper presents the design and application of a robust controller by Linear-Quadratic-Gaussian method with Loop-Transfer-Recovery (LQG LTR) at the same time to carefully attain performance and robustness objectives. To improve Stability, the robust controller has been shown to provide good performance in normal operations conditions. Objectives cannot be suitable unless the controller can perpetuate such quality in the presence of plant uncertainties or any working conditions in the hydroelectric power plants. The approach is based to synthesizing a robust controller minimizing a quadratic criterion (controller LQG) while using the Loop Transfer Recovery (LTR), to restore robustness properties of the Estimator. In this study, we applied this robust control law on the model of a Francis hydro turbine. Computer simulations are carried out to establish and compare the performance and robustness of using the Infinite horizon control (W∞), internal model control (IMC), Proportional Integral Derived (PID) and LQG/LTR controllers.

Keywords: Francis hydro Turbine, speed, LQG/LTR, parametric disturbance hydro- power plant.

I. INTRODUCTION

The robust control of the dynamic systems plays a significant role in the correct operation of the machines and the industrial processes. Many complex engineering systems are equipped with several actuators that may influence their static and dynamic behavior. The complexity of these systems and the requirements of performance increasingly more strict result in the guaranteeing need for methods of control of the performances raised with a robustness against the risks and unforeseen of the environment. The criteria of stability, robustness and performance are the objectives to be reconciled for any method of effective control. Among the most answered techniques of robust control, [1], [2] outline the solution to a range of optimal control problems. Further algorithms such as loop transfer recovery LTR were developed by [3] to improve the robustness of the more practical LQG when compared to the more robust but less practical LQR.

Since the appearance of the paper by [3] with loop transfer recovery (LTR), many papers have been written on this topic. The most notable ones for continuous time systems are [1], [4], [5] to achieve H₂ and H∞ norm specifications [1], [6]. In this paper, synthesizing a control law by Linear-Quadratic-Gaussian method with loop-Transfer-Recovery (LQG LTR) which maintains system response and error signals to within specified tolerances so that they are enable to ensure the robustness and performances for the modes of nominal and disturbed operation. In this context, we applied in simulation this controller to the system (model of hydro turbine of the hydroelectric power plant of Songloulou) [6]-[8].

This paper is organized as follows: We present in section 2 the process model on which we worked; section 3 describe the Synthesis of a robust controller by approach LQG LTR. The results obtained from simulation are given and analyzed in time and frequency domain in section 4, the obtained results are compared with the controllers PID, IMC and H∞. Finally, section 5 resumes the main conclusions obtained during the development of this work.

II. PROCEDURE FOR PAPER SUBMISSION

MODELING OF THE PLANT

For the realization of our project, we have used the model of the Songloulou hydroelectric power plant. The System modeling is presented in [7], [8]. The process is carried out by association of 4 modules: the Francis hydro turbine, the alternator, the servo-motor-servo valve and power chain, figure 1.

Fig. 1. Schematic representation of the hydro turbine driving a synchronous generator in hydro power plants.

A. Modeling of the Francis turbine model

The reduced Bond graph representation of a Francis hydro turbine shown in Figure 2 [7].

III. SYSTEM IDENTIFICATION

From the response curve seen in figure 4, the system is approximately a first order system. Using Broïda parameters, the system response time (T) and time constant is calculated following the formulas given below [9]:

\[
T = 2.8t_1 - 1.8t_2, \quad \tau = 5.5(t_2 - t_1) \tag{2}
\]

With K=12.57, T=42.84s and τ=0.538s , the transfer function of the nominal regime of the Broïda model of the system is given by:

\[
G(s) = \frac{12.57}{1 + 42.84s} e^{-0.538s} \tag{3}
\]

The first order PADE approximation of the model with time delays is given by:

\[
G(s) = \frac{-12.57s + 46.73}{42.84s^2 + 160.3s + 3.717} \tag{4}
\]

The simulation results are represented in figure 4.

IV. METHOD OF SYNTHESIS OF A ROBUST CONTROLLER BY LQG/LTR APPROACH

Consider the stochastic dynamic system of state equations:

\[
\begin{align*}
\dot{x} &= Ax + Bu + \Gamma w \\
y &= Cx + v
\end{align*} \tag{5}
\]

Where A, B, C are state space matrices of the plant and \( \Gamma \) is the disturbance, the noise of state \( w \) and the measurement noises \( v \) are assumed Gaussian noises with zero mean and covariance matrices \( W \) and \( V \) as follows:

\[
E\{ww^T\} = W \geq 0, \quad E\{vv^T\} = V \geq 0 \tag{6}
\]

\[
E\{wv^T\} = 0
\]
The problem is then to devise a feedback control law which minimizes the performance index:

$$J = E\{1 \int_{T_0}^{T} \left[ z^TQz + u^TRu \right] dt \}$$ (8)

Where $z$ is a linear combination of the system states, $Q$ and $R$ are weighting matrices.

The mathematical criterion that one seeks to minimize is [10]:

$$\min J_G \quad \text{with} \quad J_G = E\{e_x^T \hat{e}_x\} = 0$$ (9)

Where $\hat{e}_x$ is the error in estimation of the state of the system in permanent mode.

From the equations (5) and (9), we deduce the equation from evolution of the error in estimation:

$$\dot{\hat{e}}_x = A\hat{e}_x + w - K_f(C\hat{e}_x + v)$$ (10)

$$\dot{\hat{e}}_x = (A - K_f C)\hat{e}_x + [I_n - K_f]\begin{bmatrix} w \\ v \end{bmatrix}$$ (11)

By applying the theorem of the passage of a white noise in a linear system to the equation (10) and (11) we obtain the equation of continuous LYAPUNOV [3], [11]:

$$(A - K_f C)P_f + P_f (A - K_f C)^T + W + K_f V K_f^T = 0$$ (12)

Where Kalman-filter static gain $K_f$ of the optimal observer is as follows:

$$K_f = P_f C^T V^{-1}$$ (13)

Where $P_f$ obeys the algebraic Riccati equation.

$$P_f A^T + A P_f - P_f C^T V^{-1} C P_f + W = 0$$ (14)

With $P_f > 0$

The optimal control is given by: $u(t) = -K_f \hat{x}(t)$

Where $K_f$ is an optimal static feedback gain obtained by considering the LQR problem:

$$K_f = R^{-1}B^TP$$ (15)

where $P$ is the unique positive definite solution of the Riccati continuous algebraic equation.

$$PA + A^TP - PBR^{-1}B^TP + Q = 0$$ (16)

According to Figure 5, the representation of state of controller LQG is written:

$$\begin{bmatrix} \dot{x} \\ u \end{bmatrix} = \begin{bmatrix} A - BK_c - K_f C & K_f \\ -K & 0 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$ (17)

We deduce from the equation of state (17), the transfer matrix of the controller:

$$K(s) = -K_f(sI - A + BK_c + K_f C)^{-1}K_f$$ (18)

A. Loop Transfer Recovery and Choice of the weighting matrices

Approach LQG/LTR consists with calculated the KALMAN filter by a suitable choice of the matrices of variance noise $E\{w w^T\} = \mathbb{W} = \Gamma^T \Gamma$ and $E\{v v^T\} = \mathbb{V} = \rho I$ by taking of account properties of dual robustness for the choice of the parameters $\Gamma$ and $\rho$.

Where $\Gamma \in \mathbb{R}^{n \times p}$ is the process noise distribution matrix and $\rho$ is a scaled value; then in calculation, the command by return of state (command LQ) starting from an adjustment of the matrices of weighting $Q$ and $R$ so that the matrix of transfer of the open loop of the unit approaches gradually that obtained by the KALMAN filter.

A first stage of synthesis LQG/LTR relates to the choice of weighting matrices $Q$ and $R$ for the calculation of the command with return of state LQ in the following way [1], [4]:

$$Q = \Gamma \Gamma^T \text{ and } R = \rho I$$ (19)

B. Robustness Condition on the Performances in low Frequency (LF) and Robustness Condition on the Performances in High Frequency (HF)

The robustness condition on the performances is given by:

$$\sigma_{\min} \left[ C \Phi(j\omega) \Gamma \right] \sqrt{\rho} \leq \sigma_{\max} \left[ W_p(j\omega) \right]$$ (20)

Where $\Phi(j\omega) = \left[ s I - A_c \right]^{-1}$

The transfer matrix and $\sigma_{\max} \left[ W_p(s) \right]$ the largest singular value of specification on stability.

For the robustness on stability it is thus necessary, to ensure the following condition [1], [3]:

$$\omega_c = \sigma_{\max} \left[ C \Phi(j\omega) \Gamma \right] \sqrt{\rho}$$ (21)

Where $\omega_c$ is the cut-off frequency of the reverse of the singular values of the specification on stability $\left[ 1/\sigma_{\max} \left[ W_p(s) \right] \right]$.

Asymptotic Covering

The adjustment is done by a choice of the matrices form [3]:

$$Q = Q_0 + q C C^T \text{ and } R = R_0$$ (22)

From equation (27), we can rewrite the theorem of the dual LTR in the following way [3], [5]:

Fig. 5. Functional diagram of Kalman filter.
Design of a Robust Controller by LQG/LTR Formalism for Francis hydro Turbine Driving a Synchronous Generator

\[ \lim_{\xi \to \infty} K(s)G(s) \to C\Phi K_i \]  

(23)

Figure 6 shows the configuration of a perturbed closed-loop system.

Where \( u \) is the commande, \( y \) is the process output, \( e \) is the loop’s error, \( G(s) \) is stamp transfer matrix of the system, \( K(s) \) is the transfer matrix of the controller and \( \Delta(s) \) is the process uncertainty at the process output.

The maximum singular value of \( \Delta(s) \) is given by (24):

\[ \sigma_{\max} \left[ \Delta(s) \right] = \sigma_{\max} \left( \left[ [I + \Delta(s)].G(s) \right].G^{-1}(s) \right) \]  

(24)

\[ \sigma_{\max} \left[ \Delta(s) \right] = \sigma_{\max} \left( \left[ [I + \Delta(s)].G(s) \right].G^{-1}(s) \right) \]  

The frequential gauge of the specifications is represented on figure 7 and figure 8.

**Fig. 6. Feedback configuration of a closed-loop system subjected to multiplicative disturbances.**

**C. Robust Stability and Robust Performances**

The conditions of robustness on stability and the performances corresponding to the parametric disturbance \( \Delta(s) \) are:

\[ \sigma_{\max} \left[ T(s) \right] < \frac{1}{\sigma_{\max} \left[ W_i(s) \right]} \]  

(25)

\[ \sigma_{\max} \left[ S(s) \right] \leq \frac{1}{\sigma_{\max} \left[ W_p(s) \right]} \]  

(26)

Where \( T(s) \) is the nominal closed loop transfer matrix and \( S(s) \) is the sensitivity matrix given by [12], [13]:

\[ T(s) = K(s)G(s) \left[ I + K(s)G(s) \right]^{-1} \]  

(27)

\[ S(s) = \left[ I + K(s)G(s) \right]^{-1} \]  

(28)

The stability specification matrix \( W_i(s) \) is defined by:

\[ \sigma_{\max} \left[ \Delta_m(s) \right] \leq \sigma_{\max} \left[ W_i(s) \right] \]  

(29)

**V. DESIGN OF LQG/LTR CONTROLLER FOR FRANCIS HYDRO TURBINE**

**A. Choice of the specifications on stability and the performances weighting matrices**

On the basis of the criteria previously established, the stability specification \( W_i(s) \) and the performance specification \( W_p(s) \) are represented as follow:

- Stability specification.
  \[ W_i(s) = 0.9(1 + 0.03s) \]  

(30)

- Performance specification.
  \[ W_p(s) = \frac{(1 + 0.1s)}{0.1s} \]  

B. Robustness conditions

The robustness conditions for the speed hydro turbine are represented in figure 9.

**Fig. 7. Maximum singular value of \( W_i(s) \).**

**Fig. 8. Maximum singular value of \( W_p(s) \).**

**Fig. 9. Robustness conditions.**

**C. Performances condition in high frequency (HF)**

To guarantee this condition it is necessary to ensure the condition of robustness on stability in HF:

**Fig. 10. Robustness condition on the performances in high frequency.**

D. Performances condition in low frequency (HF)
Fig. 11. Robustness condition on the performances in low frequency.

Figures (10) and (11) famous determination of $\Gamma$ and $\rho$, by test-error starting from the preceding conditions of robustness is done. One obtains thus $\Gamma=\{1,0\}$ and $\rho=0.000015$.

E. Loop transfer recovery

Fig. 12. The recovery of the loop gain for $q=0$.

Fig. 13. The recovery of the loop gain for $q=109$.

According to figures 12 and 13, one observes that the principal gains of $L(s) = K(s)G(s)$ tends towards the principal gains of optimal observer $L_{PK}(s) = C(sI - A)^{-1}K_{F}$ with a total covering.

Fig. 14. Principal gains, Sensibility and robustness conditions.

Figure 14 showed that the robustness conditions on stability and the performances are satisfied: the stability is guaranteed if the largest singular value of closed loop transfer matrix function $1/\sigma_{\text{max}}[T(s)]$ is lower than the upper bound of the largest singular value of the model uncertainties $1/\sigma_{\text{max}}[W(s)]$.

The singular values of the sensitivity $\sigma_{\text{max}}[S(s)]$ are below the robustness condition on performances $1/\sigma_{\text{max}}[W_{P}(s)]$ what allows the rejection of the disturbances and guarantees the performances desired in the synthesis. The final controller is then given by

$$K(s) = \frac{5.184s^3 + 123.1s^2 + 388.4s + 8995}{s^4 + 62.51s^3 + 283.6s^2 + 290.85s + 0.02908} \quad (32)$$

Figure 15 shows the simulink model of the closed-loop of the power plant in the presence of the LQG/LTR controller.

VI. RESULT AND DISCUSSION

Figure 16, 17, 18 and 19 shows the step responses of nominal and perturbed regimes of hydro turbine plant.

Fig. 15. Simulink model of the closed-loop of the power plant in the presence of the LQG/LTR controller.

Design of a Robust Controller by LQG/LTR Formalism for Francis hydro Turbine Driving a Synchronous Generator

The stability of all regimes (figure 16, 17,18 and 19) show a good performance and a fast response time with LQG/LTR controller. It is noted that our obtained results are very encouraging with the PID, CMI and $H_{\infty}$ controllers reported by [6].

Figure 18 shows that the LQG/LTR controller has improved the speed of hydro turbine where reduction of overshoot and oscillation are obtained.

Figure 19 shows that disturbance rejection due to the LQG/LTR controller is faster than the $H_{\infty}$, IMC and PID.

Figure 20 shows that the disturbance rejection responses of the nominal plant $G$, the perturbed plant $G_1$, $G_2$, and $G_3$.
Table 3, Table 4, Table 5 and Table 6 shows that the LQG/LTR controller has eliminated the steady state error faster than the PID, IMC and $H_\infty$ controllers where reduction of overshoot and oscillation are obtained. Settling times of system characteristic component parts by using LQG/LTR controller are shorter, and the stability of the system is better by applying this optimal control method.

VII. CONCLUSION

In this paper a robust controller LQG/LTR to achieve the benefit of feedback in the face of uncertainties has been investigated and successfully applied to a hydro turbine driving a synchronous generator. From the simulation results, it is clear that, the LQG/LTR control exhibits better performance for rotational speed responses than the PID and IMC and $H_\infty$ control.
