Modifying Exhaust After-Treatment Device for Complying with Future Emission Norms

Jayvir Shah, Vikash Patel

Abstract: Day to day increase in air pollution is one of the serious issues nowadays. One of the main contributors is automobile emissions. It contains gases like carbon dioxide, carbon monoxide, hydrocarbon, nitrogen oxides, and particular matters. In order to address such issues, this paper is focused on the reduction of emissions by modifying the design of an exhaust after-treatment device. The analysis is carried out on a 4-stroke single-cylinder 149cc FZ-S BS4 bike two-wheeler gasoline engine. CO and HC emissions absorbed by an aqueous solution having different TDS of aqua 90ppm RO water, 1000ppm Municipality water, and 10000ppm seawater. Such aqueous solution contains calcium powder and activated carbon in 10:0.5:0.5, 10:1:1 and 10:2:2 in proportion respectively. An optimum solution derived which having a mixture of 10:1:1 proportion having 10000ppm seawater is derived which shows reduction in CO by 50% and HC emission by 40% as compare conventional muffler exhaust emission. The IoT device is used with the MQ-7 sensor to measure CO emission from a modified device and data obtained are compared with PUC (Pollution under control) certified center. This research is to optimize emission from the existing gasoline engine, from April 2017 BS4 is implemented in INDIA nationwide & BS6 will be going to implement by 2020. From April 2017 manufacturer are not allowed to build new engines below BS4 standard but customer those who are having an older version of engines are not having any effect of BS4 & their engines are still emitting more pollution than the current emission norms. More than 100 million of two-wheeler engines were sold in between Feb ‘06- March’17. This study aims to provide a solution for such engines not from the manufacturer side but from the consumer side to upgrade their vehicle to satisfy future emission norms so that human health will be less affected by such emissions.

Keywords: Air pollution, Exhaust emission, Exhaust after-treatment device, Activated carbon, Internet of things.

I. INTRODUCTION

One of the exhausts after-treatment device is an aqua silencer. It is used to reduce harmful emission from the automobile. The diagram of it is shown in figure 1. It contains a perforated tube with holes of different diameters and installed at the end of the exhaust pipe. On the periphery of its activated charcoal layer is provided. A metallic mesh covers the activated charcoal layer. Such assembly is placed in container consists of aqua. A small port is provided at the top of the container for exhaust purpose and it is open to the atmosphere. Also, in order to drain the water periodically drain plug is provided at the bottom of the container.

2. Filler plug
3. Charcoal layer
4. Perforated tube
5. Wire mesh
6. Drain plug

This design of an exhaust after-treatment device is having few drawbacks. When exhaust gas chemically reacts with aqua it creates carbonic acid which is not desirable. Modified exhaust after-treatment device address this issue. [1]

Also, the catalytic converter is used as an exhaust after-treatment device that uses expensive material like platinum, rhodium as a reduction catalyst also has a drawback of warming up the temperature as well which also overcomes by the modified design of exhaust after-treatment device. [1]

II. LITERATURE REVIEW

Figure 1 Conventional aqua silencer design [1]

A few researchers had done research for modification of exhaust after-treatment device contain aqua. Some of them worked on the reduction of noise and the opacity of silencer.

Raimo kabral et. al. developed a micro-perforated tube backed by the local reacting cavity. The aim is to match theoretical optimum cremer impedance in the frequency range of interest. High damping >30 dB achieved at cremer impedance. Simulation and experimental work carried out on a light-duty vehicle. [2]

P Krause et. al. investigate on the semi-active muffler. The internal geometry of it has been modified as per engine condition during driving. This design gives anti-noise or modulates pulsating exhaust gas flow in order to smoothen the gas pressure and to give sound attenuation. [3]

S. Martin et. al. designed silencer for sound attenuation. There are two types of mufflers a reactive type of dissipative type. A reactive muffler designed to reduce sound by sending sound back to the engine component due to area discontinuity. For two moderate frequencies, it provides good sound attenuation. [4]

Karthikeyan et. al. investigates that fe-zeolite catalytic converter will reduce hydrocarbon and carbon dioxide emission for the range of brake power from 2-18 kW. [5]

Ferhat kaya et. al. had done an experiment to overcome the drawback of the catalytic converter during cold start working conditions and found that phase change material
Modifying Exhaust After-Treatment Device For Complying With Future Emission Norms

RT50 reduces carbon monoxide emission 0.21% by volume analysis during first 200sec when the ambient temperature is around 12.50c. [6]

Bagus et. al. uses the catalyst as manganese coated copper CuMn and found that as cell number increases CO emission decreases but not having an effect on HC, CO2 emission. [7]

III. DEVELOPMENT OF MODIFIED EXHAUST AFTER-TREATMENT DEVICE

The modified design of the exhaust after-treatment device is as shown in figure 2. It shows a rectangular box having dimension 15cm x 15cm with a height of 60cm. Dimensions are constrained to reduce drag force while driving a vehicle by attaching such a device at the backside of the vehicle.

Figure 2: Cad model of modified exhaust after-treatment device

The detail assembly view is shown in figure 3. It shows upper cover with dimension 17cm x 17cm having 2 holes of 6mm diameter at each side for nut attachment and two holes of 1inch diameter at center act as an inlet and exhaust for the device. A gasket of the same dimension is provided in order to prevent leakage of exhaust gas. A partition of dimension 58cm with a thickness of 3mm is provided to divide inlet and the outlet port.

Figure 3: Assembly of a modified exhaust after-treatment device

A transparent plastic sheet of 3mm is used to prepare such a model in order to observe experimental changes at a macro level and a gasket of 6mm rubber is attached at the top in order to prevent leakage of gases. A one-inch pipe of PVC with maximum transparency is used to attach silencer with the device.

Figure 4: Assembly step-1

Insert the partition as shown in figure 4 in the groove provided at the center of the enclosure. Fasten nuts in the holes provided in the uppercase. Insert the flexible pipe from the inlet port provided in the uppercase as shown in figure 5.

Figure 5: Modified exhaust after-treatment device

MQ-7 carbon monoxide emission measurement sensor is used with a bolt IoT platform in order to measure CO emission coming out from the exhaust after-treatment device and exhaust tailpipe. Figure 6 shows the bolt IoT device with the MQ-7 sensor.

Figure 6: Bolt IOT device with MQ-7 sensor

Bolt IoT step by step connection is described as per figure 7. Step-1 Assemble the circuit using bolt hardware module here connect GND pin of the bolt with GND pin of the sensor and connect 5v pin output of bolt to VCC input of sensor. Step-2 connect AO means analog output pin with 0 pins of bolt hardware. Step-3 set data collection rate for this study it is taken as 5 min per signal.

Figure 7: BOLT IOT device setup
IV. RESEARCH METHODOLOGY

- CO emission measurement from MQ-7 sensor and comparison of data with PUC data without a modified exhaust after-treatment device.
- Absorption of CO by different TDS of water (a) 90ppm RO water (b) 1000ppm municipality water (c) 10000ppm seawater.
- Check for carbonic acid formation by using PH paper.
- Derive the best CO absorption water or aqua for a mixture.
- Prepare a mixture of calcium powder and activated carbon with best absorption water in the following proportion (a) 10:0.5:0.5 (b) 10:1:1 (c) 10:2:2.
- Check for carbonic acid formation by using PH paper.
- Derive the best CO absorption mixture.
- Validate it with PUC for the same mixture proportion.

V. EXPERIMENTAL SETUP

Figure 8 shows the first step to attach the exhaust after-treatment device to the bike. In this study 4-stroke, single-cylinder FZ bike is used for experimental work. A PVC pipe of a 0.5-inch diameter of 10cm in length is attached at the back of the silencer. Silencer output is also of the same diameter. In order to fix it on silencer exhaust PVC pipe is heated and due to heat its diameter gets extended and fixed in silencer exhaust to form tight leakage less joint as it cools. In the same manner, a flexible pipe is attached to the PVC pipe.

The next step is to attach an enclosure with the above assembly. The flexible pipe is attached with the inlet port of enclosure and solution of aqua: calcium carbonate powder: activated carbon in a proportion of 10:1:1 filled in the enclosure up to 75%. Bolt IoT device is placed at the exit port with one connection with power bank to get power input and another connection with the MQ-7 sensor in order to measure carbon monoxide emission. Figure 9 shows the assembly of an exhaust after-treatment device.

VI. DESIGN OF EXPERIMENTS

- DOE is done by using software Minitab V19.0
- Type of design: 2 Level factorial
- No. of factors: 3
  - The temperature at exhaust from the silencer
    - 28°C to 48°C
  - The proportion of calcium and activated carbon in mixture
    - 0.5 to 2
  - TDS of aqua
    - 90 to 11100

The experiment is carried out by aiming to provide a solution from easily available chemicals. Ro water having nearly 100ppm Municipality water having tds 1000 ppm and 10000 ppm seawater is used in order for preparation of the aqueous solution. Figure 10 shows the reading of the TDS meter for seawater which is near about 11100ppm.

The first analysis is carried out by filling a modified exhaust after-treatment device with such aqua then out of these three aquae which absorbs CO in optimum amount will be considered for preparation of the mixture.

Following full factorial results generated through Minitab

In this research optimizing the result means which combination of parameters will give minimum CO emissions and as per optimizer it shows at 11100TDS with 2.0 proportion of parameters and at 480C exhaust silencer temperature CO emission is minimum.
VII. RESULTS

The experiment was conducted on a 4 stroke single cylinder YAMAHA FZ 150cc bike. Measurement of emission carried out from 10 a.m. to 5 p.m. Figure 10 shows a glimpse of an experiment carried out.

Figure 11: Experiment on FZ bike with a device

Graph of time stamp v/s ppm_data generated by using bolt IoT device. Data collected every 5 minutes of the time interval. From 10 a.m. to 2:10 p.m. data obtain without attaching an exhaust after-treatment device and from 2:10 p.m. to 4:50 p.m. with exhaust after-treatment device as shown in figure 11.

Figure 12: time v/s CO data from BOLT IOT device

The graph indicates that without exhaust after-treatment carbon monoxide emission was 90 to 100 units. After attaching the exhaust after-treatment device it will reduce by 50 – 55 units. Nearer to 2 p.m. graph was downward in nature because the experiment carried out with different TDS aqueous solution and found that solution with higher TDS will reduce emission drastically as shown in the graph. Further two spikes were observed left side and right side to 4 p.m. is because the device was open for PH testing by using PH paper.

Figure 13 (a) and (b): PH value measurement

Figure 13 shows the PH reading of aqueous solution consisting of 11100 ppm water solution and obtain that PH value is between 5-6 which indicates acidic in nature. In order to convert such acidic solution into a basic and further reduction in CO emission calcium power in terms of limestone and activated carbon in 10:0.5:0.5 proportion added means 10part of aqua with 0.5 part of calcium powder and 0.5 part of activated carbon but still reaction remains acidic in nature. Hence increases the proportion by 10:1:1 and after 3hrs of the experiment. PH value obtains is 9 as shown in the second figure of figure no.13 which is >7 means solution is basic in nature. Further proportions increase 10:2:2 in order to check whether a further reduction is possible or not and found that the same effect is observed as observed in 10:1:1.

In order to validate data obtained from bolt IOT device and also to check its effect on the HC emission PUC test was conducted with and without exhaust after-treatment device. PUC certificate of the bike without exhaust after treatment is shown in figure 14.

Figure 14: PUC without modified exhaust after-treatment device

Figure 14 shows as per PUC norms permissible limit of CO emission is up to 3.5% and the permissible limit of HC emission is 4500 ppm. Without using exhaust after-treatment device CO emission observed 1.314% and HC emission observed 2857 ppm. Figure 15 shows the PUC certificate obtain after attaching an exhaust after-treatment device.

Figure 15: PUC with modified exhaust after-treatment device
Modifying Exhaust After-Treatment Device For Complying With Future Emission Norms

As per figure 15, it shows that CO emission reduces from 1.314% to 0.514% HC emission reduces from 2857ppm to 1557 ppm value. Table 1 indicates a comparison of readings from PUC and by using bolt IOT device with and without exhaust after-treatment device.

- From the DOE it indicates that at 11100TDS and 10:2:2 proportion minimum CO emission is observed but such DOE is carried out at extreme minimum and maximum value. And the intermediate value is not having any results in it. As per table 1 random results are obtained to check the effect of proportion 10:1:1 and TDS 1000 of municipality water and as per table 1 it is concluded that 10:1:1 is the optimum result for mixture preparation.

- As per table 1, it indicates that without attaching modified exhaust after-treatment device MQ-7 sensor measures average 100units of CO which is equivalent to 1.314% of volume CO as per PUC comparison.

- Further experiment analysis is carried out by filling 90ppm RO water, 1020ppm municipality water, and 11100 ppm seawater in modified exhaust after-treatment device and lowest emission observed in the highest TDS seawater which is 70unit by MQ-7 sensor equivalent to 0.919% of volume CO as per PUC comparison.

- The acidity of the mixture checked by the PH test paper and it is found that when exhaust emission chemically reacts with aqua and becomes acidic in nature as PH test paper shows value around 5.5 which is less than 7 means acidic in nature.

- In order to make the solution basic in nature and further absorption of CO from exhaust calcium (limestone) and activated carbon mixed in seawater in the following proportion respectively 10:0.5:0.5, 10:1:1 and 10:2:2.

- It is found that proportion 10:0.5:0.5 is able to reduce CO emission but not adequate to make the solution basic in nature, while proportion 10:1:1 is able to give optimum result by reducing CO up to 50unit by MQ sensor equivalent to 0.514 % by volume of CO as per PUC comparison.

- Also experiment carried out with proportion 10:2:2 but it shows the same effect as produced by proportion 10:1:1 and hence it is considered as an optimum aqueous solution to reduce exhaust emission.

- Table 2 indicates a comparison of optimum mixture value with PUC data obtained and concludes that CO is reduced from 1.314% to 0.514% while using 10:1:1 aqueous solution in a modified exhaust after-treatment device. The same reduction is observed from the MQ-7 sensor it indicated a reduction of CO from 50units to 50units which validate data obtain by the sensor.

- From PUC data it can be concluded that CO emission reduced up to 60% while MQ-7 data indicate it reduces by 50%.

- Also, the PUC certificate indicates that HC emission reduces from 2800 to 1600ppm means almost 40% reduction in HC emission while using a modified exhaust after-treatment device.

ACKNOWLEDGMENT

We thank Dr.A.V.Doshi sir and Dr. Ratnesh Shukla sir for comments that greatly improved the manuscript.

We would also like to show our gratitude to Mr.Anand Gadhvi owner of the PUC center AVAD to give permission for measurement of emission in his premises.
